

EXTERNAL ANTENNA FOR AMBIENT LOCKIT & TINY LOCKIT

This antenna utilizes a helical element to greatly reduce the physical length of the antenna housing and is ideal for small products where cosmetic or functional requirements dictate a compact, aesthetically pleasing antenna package. Despite their tiny size, these antennas are ruggedly constructed and able to withstand punishing environments just like our larger whips. They attach via an SMA connector.

Technical Details

- Reduced-height helical whip
- Excellent performance
- Omni-directional pattern
- Low VSWR
- Fully weatherized
- Rugged & damage-resistant
- Center Freq. 2.45 GHz
- Bandwidth 300 MHz
- Wavelength $\frac{1}{4}$ wave
- VSWR <2.0 typ. at center
- Impedance 50 Ohms
- SMA connector
- Oper. Temp. Range: -30° to $+90^{\circ}\text{C}$

Electrical specifications and plots measured on 10.16 cm x 10.16 cm (4.00" x 4.00") reference ground plane

experience quality.

Counterpoise

Quarter-wave or monopole antennas require an associated ground plane counterpoise for proper operation. The size and location of the ground plane relative to the antenna will affect the overall performance of the antenna in the final design. When used in conjunction with a ground plane smaller than that used to tune the antenna, the center frequency typically will shift higher in frequency and the bandwidth will decrease. The proximity of other circuit elements and packaging near the antenna will also affect the final performance. For further discussion and guidance on the importance of the ground plane counterpoise, please refer to Linx Application Note AN-00501: Understanding Antenna Specifications and Operation.

VSWR Graph

The Voltage Standing Wave Ratio (VSWR) is a measurement of how well an antenna is matched to a source impedance, typically 50-ohms. It is calculated by measuring the voltage wave that is headed toward the load versus the voltage wave that is reflected back from the load. A perfect match will have a VSWR of 1:1. The higher the first number, the worse the match, and the more inefficient the system. Since a perfect match cannot ever be obtained, some benchmark for performance needs to be set. In the case of antenna VSWR, this is usually 2:1. At this point, 88.9% of the energy sent to the antenna by the transmitter is radiated into free space and 11.1% is either reflected back into the source or lost as heat on the structure of the antenna. In the other direction, 88.9% of the energy recovered by the antenna is transferred into the receiver. As a side note, since the “:1” is always implied, many data sheets will remove it and just display the first number.
